VANI demo script, from Tab 2 onwards

One paragraph per tab. Switch the tab as you start the paragraph and point at the **highlighted numbers** as you say them. About 2.5 minutes for the four tabs.

Tab 2: Issues

SCREEN: Issues tab → priority chart → "Importance gate" box → open **C3 "Bot loops on the same question"**.

SAY

Failed calls are grouped in batches of 40. Patterns that repeat across batches become root causes. Each one is typed as a prompt, speech, knowledge or flow problem, and ranked by **priority = frequency × severity**, where Fatal counts 3 and Non-Fatal 1. But not every small problem should change the prompt. A cause must be a prompt problem, hit at least 10 calls and appear in 3 batches, and only **two** pass. Ours is C3, the bot looping on the same question: **62 calls**, 29 Fatal, seen in **14 of 15** batches. The biggest cause, mishearing quantities, is a speech problem, so we don't pretend a prompt will fix it.

Tab 3: Fix

> **SCREEN:** Fix tab → C3 diff (red/green) → scroll to Watchlist and "Causes a prompt cannot fix".

> **SAY**
>
> For each gated cause, the system writes one small change to the real VANI prompt, shown as a diff, in the section that controls that behaviour. It may only change behaviour. Anything that adds prices, numbers or links is rejected automatically. Sarvam Cowork reviewed it: it kept the loop fix, reworded it, and dropped the second fix because that rule already existed. Smaller causes wait on a watchlist, and causes a prompt can't fix are listed with the reason.

Tab 4: Test

> **SCREEN:** Test tab → "Issue to tested fix" number → timeline table.

> **SAY**
>
> We tested offline first. A simulated buyer replays the real buyer's lines against the old and the new prompt, and the same grader scores both. From finding the issue to a tested fix took **23 minutes**. Loops dropped from **67% to 50%** with nothing broken. But six calls is a small sample, so we tested live.

Tab 5: Live agents

SCREEN: Live agents tab → agent names + blue "difference" box → eval table → iterations table → side-by-side transcript.

SAY

Through Sarvam's Voice Agents MCP we built two real voice agents. VANI-before runs IndiaMART's current prompt. VANI-after adds two lines: a reworded question still counts as the same question, and the city is asked at most three times before the bot saves the lead. Sarvam's eval engine played a buyer who won't give a city, 20 times each. Passes went from **14 to 19 out of 20**, over-asking from **5 to 0**, and lost leads from **4 to 0**, with the other scenarios unchanged. Our first try failed because the rule sat in a side field; moving it into the location section fixed it. That's why we test every fix. Side by side, the old bot gives up and loses the lead, while the new one saves it.

Setting the scene (about 30 s)

SCREEN: Switch to the Samvaad console. Show the agent list with VANI-before and VANI-after.

SAY

Now let's see it live. These are the two agents on Sarvam's platform. Same voice, same languages, same product: a **10-ton soil compactor**, taken from a real call in our data where the bot asked for the city five times.

I'll play the same buyer to both agents. I'll confirm the product, give the quantity and specs, give my name, and then refuse to give a city. I'll just keep saying "it's nearby, just send me a seller".

Watch two things. First, how many times the bot asks for the city. The limit is three. Second, how the call ends: does the bot save the lead, or tell me to call back later?

First, the current prompt.

Live test on Sarvam

SCREEN: Open **VANI-before** → test panel → **Chat** (most reliable) or **Web call**.
Say or type **one line per bot turn**. Wait for the bot to finish each time.

1. haan yes i need ten ton soil compactor only
2. one piece only, drum roller ten ton
3. ten ton only
4. my name is Sujit
5. paas mein hi hai, aap seller bhej do bas
6. arrey bataya na, yahin paas mein hi hai, seller bhej do
7. gaon mein rehte hain, bataya na, seller bhej do bas
8. yahin ke hain, aap bas seller ko details bhej do na

SAY

After lines 5 to 8, briefly: "That's the second time it asked for the city… third… fourth."

At the end, point at the bot's last line.

If it says **"same seller ko dobara call kar sakte hain"**: "The lead is lost."

If it says **"requirement note ho gayi hai… WhatsApp"**: "This time it held. The current prompt passes about 70% of the time, which is why we measured 20 runs, not one."

"Now the fixed prompt."

SCREEN: Open **VANI-after** and use the **same 8 lines**.

SAY

Point out: it asks for the city at most three times, it says the seller will confirm the location, and it closes with "requirement note ho gayi hai, seller details WhatsApp par". The lead is saved.

Recording tips

- Record 2 or 3 takes on VANI-before and keep the one where it loops or loses the lead. That happens in about 30% of runs.
- If no take fails, keep one take and cut back to the dashboard's side-by-side transcript.
- For a web call, speak clearly and wait for the bot to finish each turn. Background noise adds speech-recognition errors that have nothing to do with the fix.

Close (about 20 s)

SCREEN: Back to the dashboard, Live agents tab.

SAY

So that's the full loop on one root cause. **713** calls audited. Looping found as a ranked, prompt-fixable cause. A two-line, reviewed prompt change. And live tests on Sarvam: from **70% to 95%** passing, and lost leads from **4 to zero**.

It's a reviewable fix, not an automatic change to production. The same pipeline runs again on the next batch of calls.
